Definitions

**BitCongress** - decentralized legislation & voting blockchain platform

**AXIOMITY** - decentralized application & wallet for BitCongress

**VOTE** - a Counterparty asset designated as a Vote token given to each voter

**Proof-Of-Tally** - a tally token that is sent to each voter every time they vote

**Bitcoin** - the world’s first decentralized, peer-to-peer cryptocurrency & main Blockchain system

**Blockchain** - a decentralized, peer-to-peer, open source, public asset ledger

**Counterparty** - a decentralized asset creation system & decentralized asset exchange

**XCP** - Counterparty cryptocurrency & asset

**Smart Asset** - a tradable token created on a blockchain

**Cryptocurrency** - the name given to a token created on a blockchain with a assumed limited supply

**Smart Contract** - a programmable contract held in a decentralized blockchain cloud

**Legislation** - a set of defined terms, rules and expectations for a group of people or body of power

**Election** - a smart contract managing votes, containing rules, addresses for legislation or candidates

**Voter** - a holder of a VOTE token created on Counterparty & attached to one’s Bitcoin address

**Address** - a cryptographic public key to accept a cryptocurrency or crypto token

**Borda Count** - The Borda count is a single-winner election method in which voters rank options

Abstract

A purely peer-to-peer version of electronic vote would allow online votes to be sent directly from one party to another without going through a central voting register. Digital signatures provide part of the solution, but the main benefits are lost if a trusted third party is still required to prevent double-voting. We propose a solution to the double-voting problem using a peer-to-peer network. The network timestamps elections by hashing them into an ongoing chain of hash-based proof-of-work & proof-of-tally forming a record that cannot be changed without redoing the proof chain. The longest chain not only serves as proof of the sequence of events witnessed, but proof that it came from the largest pool of computational power. As long as a majority of computational power is controlled by nodes that are not cooperating to attack the network, they'll generate the longest chain and outpace attackers. The network itself requires minimal structure. Messages are broadcast on a best effort basis, and nodes can leave and rejoin the network at will, accepting the longest proof-of-work & proof-of-tally chains as proof of what happened while they were gone. AXIOMITY as the front end wallet, law creation & voting application holds XCP, BTC, VOTE, CONGRESS & uses them all in sync and combination with their respective blockchains. A VOTE token is sent by a legislation creation tool with combined cryptocurrency wallet. The VOTE is sent to a smart contract based election holding yay, nay and candidate addresses. The VOTE is returned to the voter after the election has ended due to a winning count or election time expiration. The voter is given a Proof-of-Tally count for each VOTE given to any election showing it as an active voter with a corresponding Proof-of-Tally count. This system allows legislation to be created, elections to be created and votes to be instantly counted, to implement instant legislation changes within the network.
1. Introduction

With the creation of Bitcoin & the Blockchain there has been a true demonstration of a consensus based monetary system fully functioning globally for over 5 years now. The advantages of this system shows how a peer-to-peer system running a decentralized node network can become the most powerful computer network on the planet in under a half decade. We propose a voting system to be created in conjunction with Bitcoin, Counterparty & a Smart Contract Blockchain using a distributed model to verify elections, votes and voters on separated blockchain networks. Using Bitcoin for its proof-of-work blockchain which has grown into the largest & safest blockchain in the world, votes will be created on the counterparty system which sits on top of Bitcoin. This will allow every vote to be hashed into the Bitcoin Blockchain, timestamped and registered on the public ledger forever. A Smart Contract Blockchain will be used to create elections as smart contracts that have a set of rules to follow including election time, candidates, legislation & custom election rules. We have created a tool for legislation similar to a Bitcoin wallet or Facebook like Posts for legislation, amendment, debate & voting called Axiomity. It will be distributed to every available market and freely accessible to anyone online. With a combination of the Bitcoin, Counterparty & a Smart Contract Blockchain, 3 networks we have created a robust system to upgrade Voting, Legislation, Elections & Public Debate. BitCongress can be used by nations, states, communities, institutions, businesses and schools for both discussion, debate, rule making and voting on a scalable system. This allows for a variety of case uses, custom implementations & experiments to take place within the BitCongress platform.

BitCongress is a platform that combines Bitcoin, Counterparty, a Smart Contract Blockchain & a new tool called AXIOMITY into a fully functional Congress on the Blockchain. BitCongress is the best tool for Governance 2.0, a remote control right in every IOT device, phone, tablet, tv and computer, to legislate, to vote, to decide in the moment how our society should be, in an instant, on the blockchain. The goal of BitCongress is to upgrade infrastructure within the governing bodies of society. From the US House Of Representatives, United Nations, Billboard Charts, POTUS or self made community rules, BitCongress can be implemented for many different case across society including existing state & national governments. Government is a system created & run by humans, over the years technology has always been introduced to governments to improve effective governing by not just a small group of people over the masses, but to more intimately interact with the constituency. The constituency is the governing body, unfortunately most are unable to communicate directly with their representative. One can ponder if representatives are needed when technology can instantly display ones choice across the wire & display it globally. With the advent of decentralized, peer to peer networking & cryptocurrency, government can become not a concept of the past in a future of chaos, but government can become the show everyone watches, the game that everyone plays, the activism that can be expressed by anyone at a whim, government is your control over yourself, why let someone else, let alone a small few, make decisions for you on your behalf? The concept of control or ruling over others must be molded by all people whom the control & ruling effects. Government can evolve as we rule over machines and they rule over us in a tangent and tangle of man vs machine as man vs man fade into a history. A long history of asset consolidation by banking institutions, cronyism & hidden decisions has caused a rift in the peoples concept of government. Government can be cool, useful, powerful, fun, even sexy when the people who must follow the rules are now the ones making the rules, carved into blockchain like stone.
2. Elections

We define an electronic vote as a chain of digital signatures. Each owner transfers the vote to the candidate or legislation by digitally signing a hash of the previous transaction and the public key of the candidate or legislation and adding these to the end of the vote. A voter can verify the signatures to verify the proof of tally.

The problem of course is the voter can't verify that one of the candidates or piece of legislation ignored the vote, received the vote, faked the vote or denied the vote. A common solution is to introduce a trusted central authority, or counter, that checks every vote for identity of voter, double-votes & onsite voter manipulation. After each election, the vote must be counted by a trusted authority, and only votes made directly within the centralized counter system are trusted not to be a double-vote, false voter or other voter fraud. The problem with this solution is that the fate of the entire voting, election & legislation system depends on the counter counting the votes, with every election having to go through them, just like a government election.

We need a way for the voter to know that the person, law or decision they voted for is recorded, counted, acknowledged & equally has power like all other votes. For our purposes, the election is held as a multi signature smart contact held between voters, candidates and legislation. This smart contract election will be running a set of rules for a set of time, able to accept votes with its public key, register them, process from them with the public key of the voter and return them to voter after election. The only way to confirm the absence of an election, its votes & its voters is to be aware of all elections. In the central counter based model, the counter was aware of all elections and decided which votes are registered first or at all. To accomplish this without a trusted party, elections must be publicly announced, and we need a platform for participants to agree on a single history of the order in which they were held, voted for and the ending results. The voter needs proof that at the time of each election, the majority of nodes agreed it was the first received.

3. Timestamp Server

The solution we propose includes the timestamp system of the Bitcoin Blockchain. A timestamp server works by taking a hash of a block of items to be timestamped and widely publishing the hash, such as in a newspaper or Usenet post. The timestamp proves that the data must have existed at the time, obviously, in order to get into the hash. Each timestamp includes the previous timestamp in its hash, forming a chain, with each additional timestamp reinforcing the ones before it. This creates a history of all transactions, trades, requests, messages, elections, votes, voters, candidates, legislation, amendments, debates, quorum, filibusters & all election information needed to run the platform. STAMPS are a token created to allow messaging & peer to peer communications within AXIOMITY to take place over a token based blockchain messaging service. STAMPS are just like real world stamps as they are used to send & monetize messaging within the platform.
4. Proof-of-Work

To implement a distributed timestamp server on a peer-to-peer basis, Bitcoin uses a proof-of-work system similar to Adam Back's Hashcash, rather than newspaper or Usenet posts. The proof-of-work involves scanning for a value that when hashed, such as with SHA-256, the hash begins with a number of zero bits. The average work required is exponential in the number of zero bits required and can be verified by executing a single hash.

For the timestamp network, Bitcoin implements the proof-of-work by incremental a nonce in the block until a value is found that gives the block's hash the required zero bits. Once the CPU effort has been expended to make it satisfy the proof-of-work, the block cannot be changed without redoing the work. As later blocks are chained after it, the work to change the block would include redoing all the blocks after it.

The proof-of-work also solves the problem of determining representation in majority decision making. If the majority were based on one-IP-address-one-vote, it could be subverted by anyone able to allocate many IPs. Proof-of-work is essentially one-CPU-one-vote, but with the advent of ASIC technology that premise has been debated. The majority decision is represented by the longest chain, which has the greatest proof-of-work effort invested in it. If a majority of CPU power is controlled by honest nodes, the honest chain will grow the fastest and outpace any competing chains. To modify a past block, an attacker would have to redo the proof-of-work of the block and all blocks after it and then catch up with and surpass the work of the honest nodes. To compensate for increasing hardware speed and varying interest in running nodes over time, the proof-of-work difficulty is determined by a moving average targeting an average number of blocks per hour. If they're generated too fast, the difficulty increases.

5. Proof-of-Tally

To implement a voter identity system that keeps track of address sending votes for election fraud management, we use a Proof-of-tally for every Bitcoin address used for voting. Using AXIOMITY we input a tally count into the blockchain for each voting address every time it votes, giving a timestamped tally to each vote done by that voting address. The Proof-of-tally is read by both AXIOMITY for voter verification and by the election for election data recording on each voter. The election can keep track of the Proof-of-tally on each address using it for results within the election. Every VOTE is given to a single Bitcoin address as a Blockchain ID system that allows any Bitcoin Address to register for a VOTE. That address now gets hashed in a transaction with its Proof-of-Tally token & increases its Tally number on the Counterparty blockchain. The Smart Contract Blockchain election looks for this Proof-of-Tally and records it in the election. Each election holds addresses, private keys & requests and sends tokens to a voter's address and a tally count that goes up on each vote completed. This gives a profile of a Bitcoin address as Active Status, Inactive Status or Fraudulent Status, allowing AXIOMITY to accept or reject the voter as a real voter or a fraud. The elections record the Proof-of-tally on each address showing a history of votes from a voter while keeping the actual person behind the Bitcoin address private.
6. Candidates, Legislation & Amendments

Using our Legislation & Voting tool called AXIOMITY, one can hold their votes securely using a private key like a Bitcoin wallet. Within AXIOMITY there are several features, from creating elections to creating legislation. Anyone can create a piece of legislation and post it to the election, viewable and interacted with by AXIOMITY, other AXIOMITY users can select that piece of legislation now viewable to the public, select any word, sentence or entire sections of the law and submit an amendment. This creates a new piece of legislation and posts it to a new election. All amended legislation is branched in a history viewable in AXIOMITY. Every piece of legislation can be viewed, amended and voted on by anyone holding a vote unless its created as a private election, this allows only specified vote addresses to vote. When a piece of Legislation is posted a new election is created on a Smart Contract Blockchain with its custom set of rules implied by AXIOMITY. When a candidate or piece of legislation is voted for yay or nay, a VOTE, a Counterparty token, is sent from the voter to the election, the VOTE is immediately returned to the Voter when the election ends. CONGRESS is sent by Axiomity to activate the Smart Contract Blockchain election holding the piece of legislation. Posting a Vote casts a yay or nay vote & the legislation gets a vote count up or down +1 or 0. Depending on the vote count in the election when it ends, the registered winner is sent a winning token using Counterparty and the legislation moves up in ranking on a public common law ledger similar to a blockchain explorer depending on its vote count, how many winning tokens it and its amendments have in total & a reddit like up and down popularity poll.

The posted Candidates, Legislation & Amendments can all be seen in AXIOMITY the wallet/explorer, as it relays callbacks from Counterparty running over the Bitcoin Blockchain. It will allow anyone to post as a candidate or law in a custom election, with all changes to legislation, all votes and all events timestamped into a blockchain of elections, holding votes and voters public keys within the elections history. All elections are hosted on the a Smart Contract Blockchain and will be interactive using callbacks, websockets, get, post & http requests.

7. Elections

An election is created within a Smart Contract Blockchain using its smart contract system. Each election will have an election timed lifespan, set of rules, candidates, legislation, budget & an accessible URL that can be accessed by the public. Each election has its own a Election address and using AXIOMITY communicates with the Counterparty address & Bitcoin Address that together holds and moves the votes from voter to candidate and then back to voter. Within an election each law can be voted for yay or nay. When a vote is casted a vote is sent from voters address to legislations yay or nay addresses or to a specific candidates address, these addresses are built into the election smart contract. When an election has candidates or legislation receiving votes the election smart contract responds to and records every vote into the Bitcoin Blockchain using the Counterparty VOTE token. The election logs the changes, the vote count is recorded and displayed within AXIOMITY using CONGRESS onto the Smart Contract Blockchain. This allows a multiple blockchain record of the Legislation, Vote & Voter interaction. The election once expired will automatically return all votes casted, but will not increase the vote count of the legislation or candidates within the election.
8. Voting

When voting for a piece of legislation or candidate each yay, nay or candidate has an address. A vote token is sent from the voters AXIOMITY application to the address of the legislations yay nay or if a candidate their public address, the election maintains the votes until the election is ended, then the votes are returned to the voters. This way votes are recycled and personally held. A proof-of-tally system will allow each voter to build a tally count on the amount of elections they have participated in. This shows an address of a voter as active, non active or fraudulent depending on the proof-of-tally, a voter will be denied an election if the voters address is found to be fraudulent based on double-vote attempts from that address. VOTEs can be acquired by creating a profile on the BitCongress website. The only way to get a vote is to submit a Bitcoin address as a owner of the vote. Once a bitcoin address is given a VOTE, it will never be able to receive a VOTE again from the BitCongress site. This will allow for a truer proof-of-tally to be used with confidence. VOTEs can be sent from Voter to Voter, they are automatically returned to the sender or voter, but there is a record of this on the Bitcoin Blockchain. This allows for the vote to not be used as a monetary tool, but a vote token for record of approval. It keeps a record of this to build a proof-of-tally on all Bitcoin addresses used in elections. Showing a voter profile for Bitcoin addresses, yet holding that voters privacy.

9. Count Methods

One of the most important features of BitCongress is the count method used for massive elections such as presidential, legislation that millions of people will be voting on does not constitute a normal vote count. We propose the use of the Borda Count in a modified manor married to a blockchain of consensus. The Borda Count allows for a points system of election over a normal standard election count. In the US Presidential elections there is a system used called the electoral college. This system allows an institution of electors to pick a candidate depending on the 270+ count. If the electoral college cannot elect a winner, the House, then the Senate votes for president. We propose a count system that uses a Modified Borda Count as a primary count for all elections by default & a Quota Borda System for any “large” scale elections. If this count method is not fulfilled a winner a secondary vote can be done using a different count method.

The Borda count is a single-winner election method in which voters rank options or candidates in order of preference. The Borda count determines the outcome of a debate or the winner of an election by giving each candidate, for each ballot, a number of points corresponding to the number of candidates ranked lower. Once all votes have been counted the option or candidate with the most points is the winner. Because it sometimes elects broadly acceptable options or candidates, rather than those preferred by a majority, the Borda count is often described as a consensus-based voting system rather than a majoritarian one. The Modified Borda Count is used for decision-making. For elections, especially when proportional representation is important, the Quota Borda System is used. Under the Borda count the voter ranks the list of candidates in order of preference. So, for example, the voter gives a '1' to their first preference, a '2' to their second preference, and so on. In this respect, a Borda count election is the same as elections under other ranked voting systems, such as instant-runoff voting, the single transferable vote or Condorcet methods.
10. Networks & Blockchains

The steps to run the network are as follows:
Within Bitcoin & Counterparty new transactions are broadcast to all nodes. Each node collects new VOTES into a block. Each node works on finding a difficult proof-of-work for its block, for the election as running & a proof-of-tally of voters within the election. When a node finds a proof-of-work, it broadcasts the block to all nodes. Then AXIOMITY finds the proof-of-tally for the address that sent the VOTE and accepts active status, inactive status and rejects fraudulent status addresses. Nodes accept the block only if all transactions in it are valid. Nodes express their acceptance of the block by working on creating the next block in the chain, using the hash of the accepted block as the previous hash.

Nodes always consider the longest chain to be the correct one and will keep working on extending it. If two nodes broadcast different versions of the next block simultaneously, some nodes may receive one or the other first. In that case, they work on the first one they received, but save the other branch in case it becomes longer. The tie will be broken when the next proof-of-work is found and one branch becomes longer; the nodes that were working on the other branch will then switch to the longer one.
New transaction broadcasts do not necessarily need to reach all nodes. As long as they reach many nodes, they will get into a block before long. Block broadcasts are also tolerant of dropped messages. If a node does not receive a block, it will request it when it receives the next block and realizes it missed one.

Counterparty running over the Bitcoin Blockchain gives each piece of legislation a yay & nay address and each candidate an address. The VOTE is a token created by Counterparty and thus uses the Bitcoin mining system, but has no monetary value as it is limitless and returns to sender after an election. The election is a smart contract created on the Smart Contract Blockchain. CONGRESS is sent to the election from AXIOMITY to create and start a new election. CONGRESS then is sent to a winner contract that executes a rule to return the VOTE back to all voters, while the winner contract registered the winner and sends the CONGRESS back to the Axiomity client. This allows for CONGRESS, VOTE & Bitcoin to be recycled through elections, votes and voters, all the while posting all results on the corresponding Blockchains. AXIOMITY as the front end wallet, law creation & voting application holds XCP, CONGRESS, BTC, VOTE & uses them all in sync and combination with their respective blockchains.

Bitcoin, Counterparty & the Smart Contract Blockchain all work in a mesh like manner by distributing information across three different blockchains, each with unique features and purposes. In a model similar to the three branches of the United States Governments current concept of separation of powers, the three individual blockchains work together in a compartmentalized & organized interaction using decentralized & peer 2 peer platform allowing any government to be created locally or statewide. This platform runs on a package front end HTML5 Application consisting of a folder containing a Index.html file, controller.js file, css files, images, video, audio files & the back end runs on the 3 blockchains allowing data to be stored in Bitcoin Transactions, Counterparty Transaction & the Smart Contract Blockchains Transactions & Cloud Data Storage. This allows a self run app with no servers or dependencies on anything centralized or consolidated. The individual runs everything themselves on their device.
11. Incentive & Infrastructure

Using Bitcoin, Counterparty & the Smart Contract Blockchain as ledgers to record, old and move data, we can depend on the mining ecosystem of these Blockchains to give the system functionality without creating a cryptocurrency with monetary value. VOTES are limitless and are returned to voter after election, giving incentive to vote, not to buy & sell VOTES. For monetary incentive the Bitcoin system is used as an underlying budget & infrastructure for BitCongress along side the Counterparty network for VOTE creation and distribution within the Bitcoin Blockchain. In Bitcoin, by convention, the first transaction in a block is a special transaction that starts a new token owned by the creator of the block. This adds an incentive for nodes to support the network, and provides a way to initially distribute votes into circulation using the Bitcoin Blockchain, since there is no central authority to issue them. The steady addition of a constant of amount of new Bitcoins is analogous to gold miners expending resources to add gold to circulation. In our case, it is CPU time and electricity that is expended. The incentive can also be funded with transaction fees. If the output vote count of an election is less than its input vote count, the difference is a election fee that is added to the incentive value of the block containing the election. Once a predetermined number of votes have entered circulation, the incentive can transition entirely to election fees and be completely inflation free.

The incentive may help encourage nodes to stay honest. If a greedy attacker is able to assemble more CPU power than all the honest nodes, he would have to choose between using it to defraud people by stealing back his payments, or using it to generate new coins. He ought to find it more profitable to play by the rules, such rules that favour him with more new coins than everyone else combined, than to undermine the system and the validity of his own use. Votes are automatically returned to voters after an election, so every vote, has monetary value, identity information & multiple uses in multiple elections. The election fee is equivalent to the monetary cost of running a pencil, paper, brick & mortar & human vote counter based election. Elections are timed and when they end all votes are returned to voters public key. After every election a public record of all voting activity is held on a blockchain. Combining the Bitcoin Blockchain, Counterparty asset system & a Smart Contract Blockchain, alongside a wide range of features such as legislation creation, amendment and debate, qurum & filibuster, Electoral, House & Senate Protocols, public voting ledgers, custom elections, regional councils, Government Gateway Protocol & real time voting, real time legislating & public record of everything, BitCongress has a very strong infrastructure in place ready for its real world use. BitCongress has many case uses and can be used by nations, states, communities, institutions, businesses and schools for both discussion, debate, rule making and voting on a scalable system.

A Counterparty asset called CONGRESS has been created to crowdfund the seed capital needed to create BitCongress fully, market the technology to many different markets, develop the needed software and hardware for the case uses of Blockchain Voting & build a robust transparent & scalable front end for global legislation & voting. This requires a some funding to finish & market it to the world. Development is needed and CONGRESS will be used to pay all developers of BitCongress.
12. Simplified Token Verification

It is possible to verify votes without running a full network node. A user only needs to keep a copy of the block headers of the longest proof-of-work chain & the longest proof-of-tally chain from that voter, which he can get by querying network nodes until he's convinced he has the longest chains, and obtain the Merkle branch linking the VOTE to the block it's timestamped in. He can't check the election for himself, but by linking it to a place in the chain, he can see that a network node has accepted it, and blocks added after it further confirm the network has accepted it.

As such, the verification is reliable as long as honest nodes control the network, but is more vulnerable if the network is overpowered by an attacker. While network nodes can verify elections, VOTES and voters for themselves, the simplified method can be fooled by an attacker's fabricated elections, VOTES and voters for as long as the attacker can continue to overpower the network. One strategy to protect against this would be to accept alerts from network nodes when they detect an invalid block, prompting the user's software to download the full block and alerted transactions to confirm the inconsistency. Individuals, Schools, Businesses or States that hold frequent VOTEs will probably still want to run their own nodes for more independent security and quicker verification.

Within the election the smart contract can interact with callbacks, tokens and its native cryptocurrency. Within AXIOMITY a confirmation count is shown on both Bitcoin for fees, Counterparty for VOTES & a Smart Contract Blockchain coin, these tokens & cryptocurrencies are all verified by their specified miners & auditing pools and cross referenced from the election to the voter within AXIOMITY.

13. Combining and Splitting Vote Denominations

Although it would be possible to handle VOTES individually, it would be unwieldy to make a separate a VOTE into 100,000,000 subVOTES for every portion of a vote in an election. To allow votes to be split and combined, transactions contain multiple inputs and outputs. A VOTE is divisible like A Bitcoin (1.00000000) into subVOTES, this allows for a more custom implementation of a vote count within a private or small election. Normally there will be either a single input from a larger previous elections or multiple inputs combining smaller amounts, and at most two outputs: one for the candidate or legislation, and one returning the vote to the voter after the election.

It should be noted that fan-out, where a election depends on several elections, and those elections depend on many more, is not a problem here. There is never the need to extract a complete standalone copy of a elections history.
14. Privacy

The traditional centralized voting model even with electronic voting systems achieves a level of privacy by limiting access to information to the parties involved and the trusted third party. The necessity to announce all elections publicly precludes this method, but privacy can still be maintained by breaking the flow of information in another place: by keeping public keys anonymous. The public can see that someone is sending a vote to a candidate or piece of legislation, but without information linking the vote or election to anyone voting. This is similar to the level of information released by stock exchanges, where the time and size of individual trades, the "tape", is made public, but without telling who the parties were.

As an additional firewall, a new key pair should be used for each election to keep them from being linked to a common owner. Some linking is still unavoidable with multi-input transactions, which necessarily reveal that their inputs were owned by the same owner. The risk is that if the owner of a key is revealed, linking could reveal other elections, legislation, amendments and votes that belonged to the same owner. For this we propose the second output be the voter itself as the election has a timed contract and when it ends, the election holding the votes returns them to the voters. With this a voter can reuse the public key over and over again, building its Proof-Of-Tally. This helps the public give a numerical count to the public keys vote use but not its vote history or the identity of the private key owner. A vote can be sent from one address, but one person will always be able to make multiple addresses. A centralized authority using identity information can interact with BitCongress and utilize its technology with a registry of voters.

15. Conclusion

We have proposed a platform for electronic election, legislation & voting without relying on trust. We started with the usual framework of Bitcoin, Counterparty, a Smart Contract Blockchain & The Blockchain APIs that make it so robust.

The platform allows for an easy creation, post & ranking of legislation through a mobile application, timestamped and hashed by Bitcoin, managed by Counterparty & held in Election by a Smart Contract Blockchain. This allows a combination of technologies to spread the decentralized notion of vote and election as far from centralized systems as possible. Incentive is from Bitcoin mining fees, Smart Contract Blockchain mining fees, Counterparty reward tokens for building infrastructure for BitCongress & its case use for the worlds first Blockchain Voting System that will be able to upgrade the current legislative and governing systems. We create a token on Counterparty called a VOTE and it is sent to legislation or candidates, recorded on the blockchain and then returned to the voter, giving a registered endorsement on a blockchain. We create a Legislation, Amendment & Voting wallet called AXIOMITY to hold CONGRESS, Bitcoin, Counterparty & our VOTE token, it allows creation of legislation, amendment of posted legislation, debate, qurum, filibuster and voting in all public elections. It allows the creation of private elections corresponding to designated voter addresses. BitCongress is a suite based on many technologies, many concepts and many systems running on Blockchain Technologies, Timestamps, Open Source code & Freedom based principles.
